Abstract

Background and objectives: The role of runt-related transcription factor 2 (RUNX2) in tumorigenesis and tumor progression in many cancers has been identified except for lung cancer. This study aimed to explore the expression level, functions and prognostic values of RUNX2 in lung cancer.

Methods: ONCOMINE was utilized to compare RUNX2 expression difference between cancers and normal tissue. GEPIA was used to further detect the expression pattern of RUNX2 between lung cancer and corresponding normal lung tissue. Then, the prognosis value of RUNX2 in lung cancer was evaluated through Kaplan-Meier Plots. The genomic alterations of RUNX2 neighbor genes were analyzed by cBioPortal, and GO enrichment was conducted to identify functional categories of RUNX2 and genes associated with RUNX2 alterations.

Results: ONCOMINE and GEPIA revealed the upregulated expression level of RUNX2 in lung cancer compared to normal lung tissue. Higher RUNX2 level was associated with lower progression-free survival and overall survival in lung cancer patients. GO enrichment implicated that cell proliferation, invasion and metastasis-related genes as well as the functions of cell adhesion, cell migration, and cell proliferation were significantly associated with RUNX2 alterations.

Conclusions: Our findings indicated the value of RUNX2 as a novel prognostic biomarker and a potential therapeutic target for lung cancer.

Keywords: RUNX2; Lung cancer; Bioinformatics analysis; Prognosis; Therapeutic target.

Introduction

The runt-related transcription factor (RUNX) family includes RUNX1, RUNX2 and RUNX3, which are indispensable for normal lineage-specific development.¹ Among which, RUNX2 is necessary during embryogenesis for skeletal development and is a key regulator for morphogenesis of organs like thyroid and breast.^{2–4} Moreover, RUNX2 exerts its biological functions via the activation of downstream signaling pathways such as epithelial mesenchymal transition (EMT), cell cycle, cell apoptosis, NOTCH, WNT, RAS and transforming growth factor- β (TGF- β)/Smad, *etc.*^{5,6}

RUNX2 is increasingly implicated in tumor biology for potential tumorigenicity. It was reported that enhanced RUNX2 could transcriptionally induce gene expression involved in tumor initiation, development and metastasis.⁷ For example, uncontrolled RUNX2 expression was observed in the carcinogenic process.⁵ In

melanoma, RUNX2 participated in the regulation of the EMT process.⁸ Upregulation of RUNX2 expression level could recover the cancer cell invasion in cervical cancer.⁹ Additionally, in the late-stage thyroid, breast and prostate cancer, upregulated expression of RUNX2 could accelerate bone metastasis.^{10,11} These revealed that RUNX2 could function as an oncogene and emerged as a promising therapeutic target to treat cancer. Therefore, extensive work has been done. It was confirmed that in cervical cancer, downregulated RUNX2 could slow the tumor growth and metastasis through inhibiting the cancer cell proliferation, invasion, migration, and reversing the EMT process.¹² Suppressing the expression of RUNX2 in metastatic prostate and breast cancer cells could extremely decrease tumor progression and metastasis *in vivo*.^{11,13} Knockdown of RUNX2 in esophageal carcinoma cells could obviously inhibit cell growth, migration and invasion, and increased cell apoptosis and suppressed tumor growth.¹⁴

Nearly 25% of all cancer-related morbidity was contributed to lung cancer (LC) in 2020.¹⁵ Even more dire, greater than half of all LC patients have metastasized when diagnosed (57%), which may explain the unsatisfactory 5-year survival rate (5%).¹⁵ Therefore, effective and strong prognostic biomarkers and potential drug targets are urgently needed to improve diagnosis and prognosis, and personalized drug treatments of LC.

The dysregulated expression level of RUNX2 and its relationship with LC have been partly reported. It was demonstrated that RUNX2 expression level was upregulated in lung squamous cell carcinoma (LUSC) and lung adenocarcinoma (LUAD) tissues.^{16,17} Moreover, RUNX2 overexpression could promote EMT and increase the expression of EMT related genes including TWIST1, SNAIL1 and VIMENTIN, which directly reflect an increased migratory and invasion capacity of LUAD cells.¹⁸ These results suggested that RUNX2 could serve as a candidate target for LC therapy. Actually, previous research has reported that targeting RUNX2 could inhibit LC cell growth.¹⁹ Downregulation RUNX2 expression could decrease non-small cell lung cancer (NSCLC) tumor volume and weight.²⁰ It was also reported that the proliferation, migration, and invasion of human LC cells could be repressed by downregulating the expression level of RUNX2.^{21,22}

Numerous RNA and DNA research indicated their critical role in determining the biological and biomedical functions with the development of second-generation sequencing technology.²³ Nowadays bioinformatic analyses has become one of the hottest research priorities in medicine. Specifically, bioinformatic analyses were carried out to predict gene targets and analyze their potential roles in various cancers.²³ However, biological information analysis has not been applied comprehensively to explore the potential role of RUNX2 in LC. Based on the publicly available gene information, containing gene expression, gene variation and epigenetic mutations, *etc.*, we aimed to identify the expression pattern and variation of RUNX2 in LC and explore its prognostic value and potential functions in LC. Unlike previous studies that explored the function of RUNX2 through experimental methods, the bioinformatics analyses performed in our study will provide a comprehensive evaluation of RUNX2 in LC.

Materials and methods

ONCOMINE database analysis

ONCOMINE is a database of high-throughput sequencing data of cancers (www.oncomine.org), with which we could assess and visualize the differential expression of specific genes from all avail-

ably public datasets and conduct differential expression analyses. ONCOMINE was utilized to compare the RUNX2 mRNA expression difference between clinical cancer samples and corresponding normal tissue samples. A student's t-test was used to calculate the significant expression differences between tumor and normal tissues. The cut-off values were set at a P-value of 0.05 and fold change of 2.

Gene Expression Profiling Interactive Analysis (GEPIA)

The online database Gene Expression Profiling Interactive Analysis (GEPIA) (<http://gepia.cancer-pku.cn/>) is a newly developed interactive website to analyze the RNA sequencing expression data of 9,736 tumors and 8,587 normal samples from the Cancer Genome Atlas (TCGA) and Genotype-Tissue Expression (GTEx) projects.²⁴ It was used to find the expression differences of RUNX2 between LUAD, LUSC and corresponding normal lung samples. The threshold was set as following: P-value of 0.01, fold change of 2, matched TCGA normal and GTEx data.

Survival prediction analysis of lung cancer patients

The Kaplan-Meier Plotter database (www.kmplot.com) is one of the most effective analytical tools to evaluate survival and prognosis information.²⁵ The prognosis value of RUNX2 was predicted in patients bearing LC by Kaplan-Meier Plots, which provides an assessment of gene expression data and survival information of 2,437 LC patients. The survival curve of progression-free survival (FP), overall survival (OS) and post progression survival (PPS) in patients with LUAD and LUSC was generated using the JetSet best probe set with the median as the cutoff. Log-rank test results with P-value < 0.05 were considered statistically significant.

Immunohistochemistry validation by Human Protein Atlas

The Human Protein Atlas (HPA) (<https://www.proteinatlas.org/>) is an extensive database for exploration of the expression pattern of mRNA and protein in cancer and normal tissue from a large volume of proteomics and transcriptomics data.²⁶ Therefore, the cancer and normal tissue atlas of the HPA were used to generate a list of cancer types detailing the gene and protein expression of RUNX2.

RNA extraction and real-time quantitative polymerase chain reaction (RT-qPCR)

The human LUSC cell line SK-MES-1, LUAD cell line A549 and normal lung bronchus epithelial cell line HBE were obtained from the Cell Bank of Type Culture Collection of the Chinese Academy of Sciences (Shanghai, China). HBE (control group) was cultured with dulbecco's modified eagle's medium (DMEM) (Hyclone, Logan City, UT) and SK-MES-1, A549 (experimental group) were cultured with RPMI1640 containing 10% fetal bovine serum (FBS, Gibco, New Zealand), 1% antibiotic-antimycotic (Gibco, Grand Island, NY) at a density of $3 \times 10^4/\text{cm}^2$ onto the 10-cm culture dish for 24 hours. Then total RNA was extracted from the collected cells using Trizol Reagent (Invitrogen, Carlsbad, CA), and cDNA was converted from 2 μg total RNA using 200 U of reverse transcriptase (MMLV RT) and 20 pM oligo dT (Promega Corporation, Madison, WI, USA) at 30 °C for 10 min, 42 °C for 60 min, 95 °C for 5 min, and 5 °C for 5 min. The forward primer (5-TCTG-

GCCTTCCACTCTCAGT-3) and reverse primer (5-TATGGAGT-GCTGCTGGTCTG-3) were synthesized based on the Runx2 mRNA sequence. Quantitative PCR was performed with a protocol as follows: initial denaturation at 95 °C for 10 min, followed by 40 cycles at 95 °C for 30 s, 58 °C and 72 °C for 45 s, using the Strata Gene Mx3000p (Agilent Technologies, Inc., Santa Clara, CA, USA). Each gene of interest was normalized to GAPDH and the fold change was compared relative to the control sample. Each assay was performed in triplicate. The statistical analyses were processed using the statistical software Statistical Package for the Social Sciences (version 19.0, SPSS, Chicago). The data are represented as the mean \pm standard derivation. A student's t-test was employed to analyze the differences between the control and experimental group, with $p < 0.05$ considered statistically significant.

cBioPortal analysis

The LUAD (TCGA, Firehose Legacy) and LUSC (TCGA, Firehose Legacy) datasets containing 517 and 501 pathologically reported cases, respectively, were selected for further analyses of RUNX2 using the cBioPortal (<https://www.cbioportal.org/>). The spectrum of genomic alterations included mutations, putative copy-number alterations (CNA) from GISTIC, mRNA expression z-scores (RNA Seq V2 RSEM) and protein expression Z-scores (RPPA).

Construction of a protein–protein interactions (PPI) network

The STRING database (<https://string-db.org/cgi/input.pl>) aims to collect, score, and integrate all publicly available sources of PPI information and to complement these with computational predictions. RUNX2 and the targets closely related to RUNX2 alterations (top 100) were put into STRING to build the PPI network to achieve a comprehensive and objective global network, including direct (physical) as well as indirect (functional) interactions. The cutoff of the PPI confidence score was 0.7 and the disconnected nodes were hidden.

Gene ontology analysis

DAVID (<http://david.abcc.ncifcrf.gov/>) is a database for annotation, visualization and integrated discovery.²⁷ Gene Ontology (GO) is a widely confirmed gene functional enrichment database which is generally used to explore the enriched GO terms.²⁸ GO functional annotation enrichment analysis could predict the target gene function through three aspects including biological process (BP), cellular component (CC) and molecular function (MF). Therefore, GO enrichment analysis was conducted to identify functional categories of RUNX2 and the genes closely associated with RUNX2 alterations. Enriched GO terms were identified according to the cut-off criterion of P-value < 0.05 and gene counts more than 2. The top 20 GO terms of BP, CC and MF were selected to display.

Results

The transcriptional level of RUNX2 in multiple types of tumors

The mRNA expression level of RUNX2 in multiple types of cancers was compared with that in the normal samples using the ONCOMINE database (Fig. 1). As shown in Figure 1a, the expression

level of RUNX2 was obviously increased in LC patients of three datasets. In Garber's dataset,²⁹ RUNX2 was upregulated in all LC types compared to normal samples, including LUAD with a fold change of 2.829 (Fig. 1b), LUSC with a fold change of 3.703 (Fig. 1c), large-cell lung carcinoma with a fold change of 3.051 (Fig. 1d) and small cell lung carcinoma with a fold change of 1.768 (Fig. 1e).

Association between RUNX2 expression and the clinicopathological parameters of lung cancer patients

The mRNA expression level of RUNX2 between LC and normal lung tissues was evaluated by GEPIA. The results indicated that RUNX2 expression level was significantly increased in LUAD and LUSC tissues than that in the lung tissues (Fig. 2a–b). The relationship of RUNX2 expression with LUAD and LUSC tumor stage was also analyzed, however, no significant difference was mined (Fig. 2c–d).

Increased RUNX2 expression indicated a poor prognosis of lung cancer patients

The prognostic role of RUNX2 in patients with LC was investigated using Kaplan–Meier plots. The results indicated that the upregulated RUNX2 mRNA expression level was negatively correlated with the FP and OS in all LC patients (Fig. 2e–f, $p < 0.001$). Despite a decreasing trend of PPS in patients with increased expression of RUNX2, there was no statistically significant difference (Fig. 2g, $p > 0.05$).

Increased RUNX2 mRNA and protein levels validated by HPA and RT-qPCR

The HPA database was utilized to identify the expression level of RUNX2 in different normal and cancer tissues. The results demonstrated that NK-cells, dendritic cells, T-cells, cervix uterine, tonsil, appendix, bone marrow, granulocytes, lymph node, spleen contained the top ten normal tissue expression of RUNX2 mRNA (Fig. 3a). In addition, the seven tissues achieved by comparison of RUNX2 protein expression level, were salivary gland, spleen, lymph node, tonsil, bone marrow, nasopharynx, and bronchus (Fig. 3b). Among all types of cancer, thyroid cancer, pancreatic cancer, breast cancer and LC showed the highest expression level of RUNX2 mRNA and urothelial cancer, LC, skin cancer and lymphoma presented the highest expression value of RUNX2 protein (Fig. 3c–d). Our finding demonstrated that RUNX2 mRNA and protein expression levels were both obviously increased in LC. Moreover, the increased protein expression level of RUNX2 was also detected in LUAD and LUSC tissues compared to normal lung tissues (Fig. 3e–g). As shown in Figure 3h, the LUAD (A549) and LUSC (SK-MES-1) cells revealed significantly higher expression of RUNX2 with the level of 1.850 ± 0.5075 -fold and 1.773 ± 0.3810 -fold more than that of the normal lung bronchus epithelial cells (HBE). The analysis above suggests that RUNX2 was a specificity-increased biomarker in LC.

Analysis of RUNX2 and the altered neighbor genes in lung cancer patients

The RUNX2 alterations and neighbor genes altered by RUNX2 alterations were analyzed in LUAD and LUSC using the cBioPortal database. As shown in Figure 4, RUNX2 was altered in 44 out

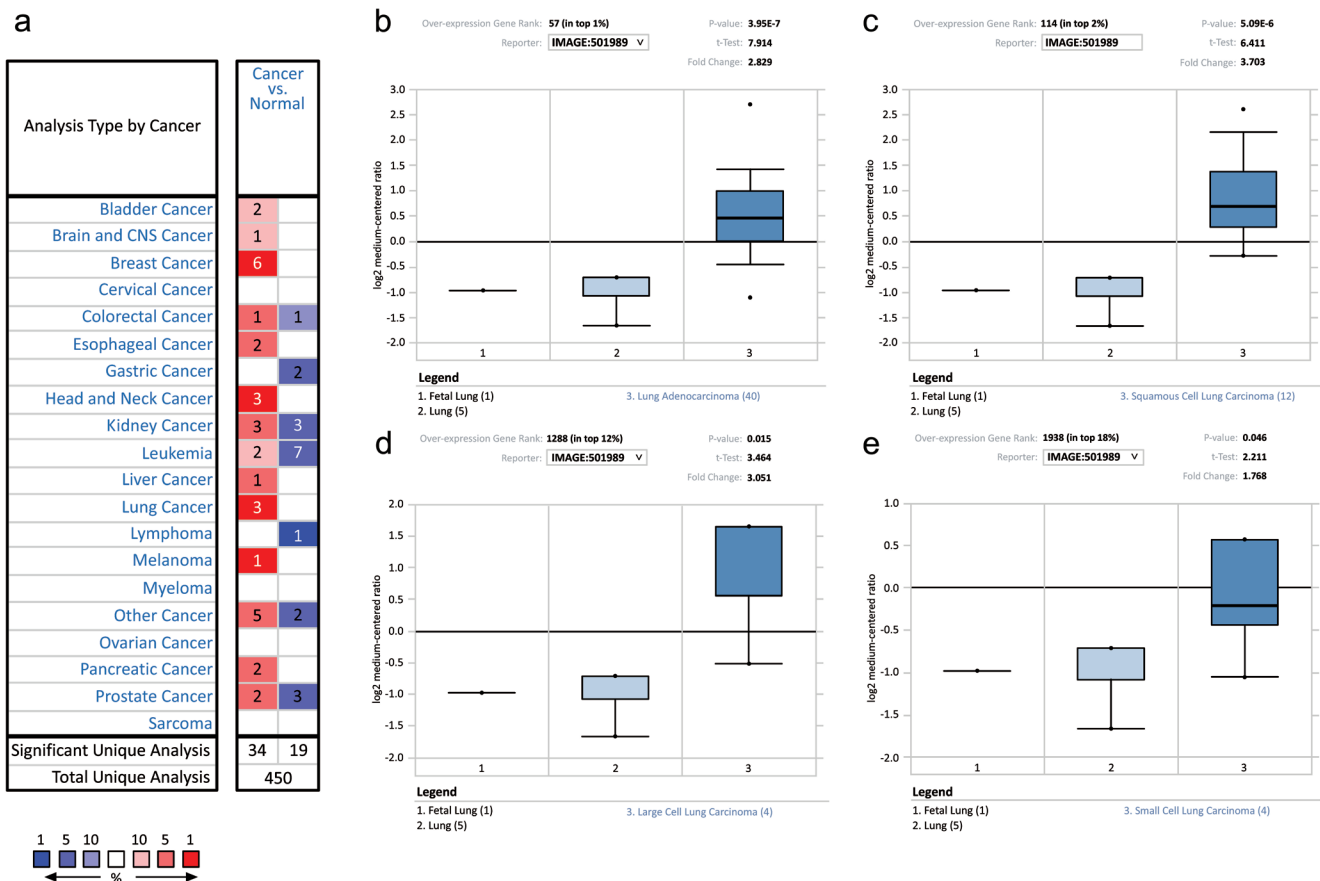

Fig. 1. The mRNA expression level of RUNX2 in various types of cancers (ONCOMINE). (a) Upregulated mRNA expression level of RUNX2 in lung cancer patients from three datasets. RUNX2 was increased in lung adenocarcinoma (b), squamous cell lung carcinoma (c), large-cell lung carcinoma (d) and small cell lung carcinoma (e) tissues compared with normal tissues.

of 517 patients with LUAD (8.51%) (Fig. 4a, c) and 42 out of 501 patients with LUSC (8.38%) (Fig. 4b, d). The top 10 neighbor genes which were most frequently altered by RUNX2 in LUAD and LUSC are listed in Tables 1 and 2, respectively, and all altered neighbor genes information is shown in Table S1–2. The results indicated that cell proliferation, invasion and metastasis-related genes DPYSL3, VCAN, ANTXR1, SULF1, COL1A2, COL3A1, COL6A3 were closely associated with RUNX2 alterations in LUAD (Table 1), and LOXL2, LTBP2, TPM1, TIMP3, COL5A1, COL6A2 were closely associated with RUNX2 alterations in LUSC (Table 2). Furthermore, the proteins in the PPI network are considered core targets in the pathogenesis of RUNX2 for LUAD (Fig. 5a) and LUSC (Fig. 5b).

GO enrichment analysis

The biological function of RUNX2 and the genes closed related to RUNX2 alterations were evaluated by performing GO enrichment analysis. As shown in Figure 6a, clinically important module genes of LUAD in the BP group were strongly enriched in cell adhesion, oxidation reduction, cell motion, extracellular matrix organization, blood vessel development, cell migration, regulation of cell proliferation and collagen fibril organization, *etc.* The genes in the CC terms were strongly enriched in membrane, extracellular matrix,

membrane fraction and cell fraction, *etc.* (Fig. 6b). The genes in the MF group were significantly enriched in polysaccharide binding, oxidoreductase activity, acting on peroxide as acceptor and growth factor binding, *etc.* (Fig. 6c). For LUSC, the clinically significant module genes in the BP group were significantly enriched in cell adhesion, extracellular matrix organization, response to wounding, vasculature development, blood vessel development, collagen metabolic process, collagen fibril organization, cell-substrate adhesion, oxidation reduction, regulation of cell motion, blood vessel morphogenesis, regulation of cell migration, *etc.* (Fig. 6d). The genes in the CC group were mainly enriched in collagen, extracellular matrix, cell surface, *etc.* (Fig. 6e). And the genes in the MF group were significantly enriched in extracellular matrix structural constituent, calcium ion binding, growth factor binding, metalloendopeptidase activity, cytokine binding, integrin binding, *etc.* (Fig. 6f).

Discussion

Functional genome analysis revealed that gene expression is far more complicated than expected and required an ongoing and widespread regulatory landscape.³⁰ Tumor initiation, progression and metastasis are an outcome of deregulation of multiple signaling pathways via the abnormal function of transcription factors.

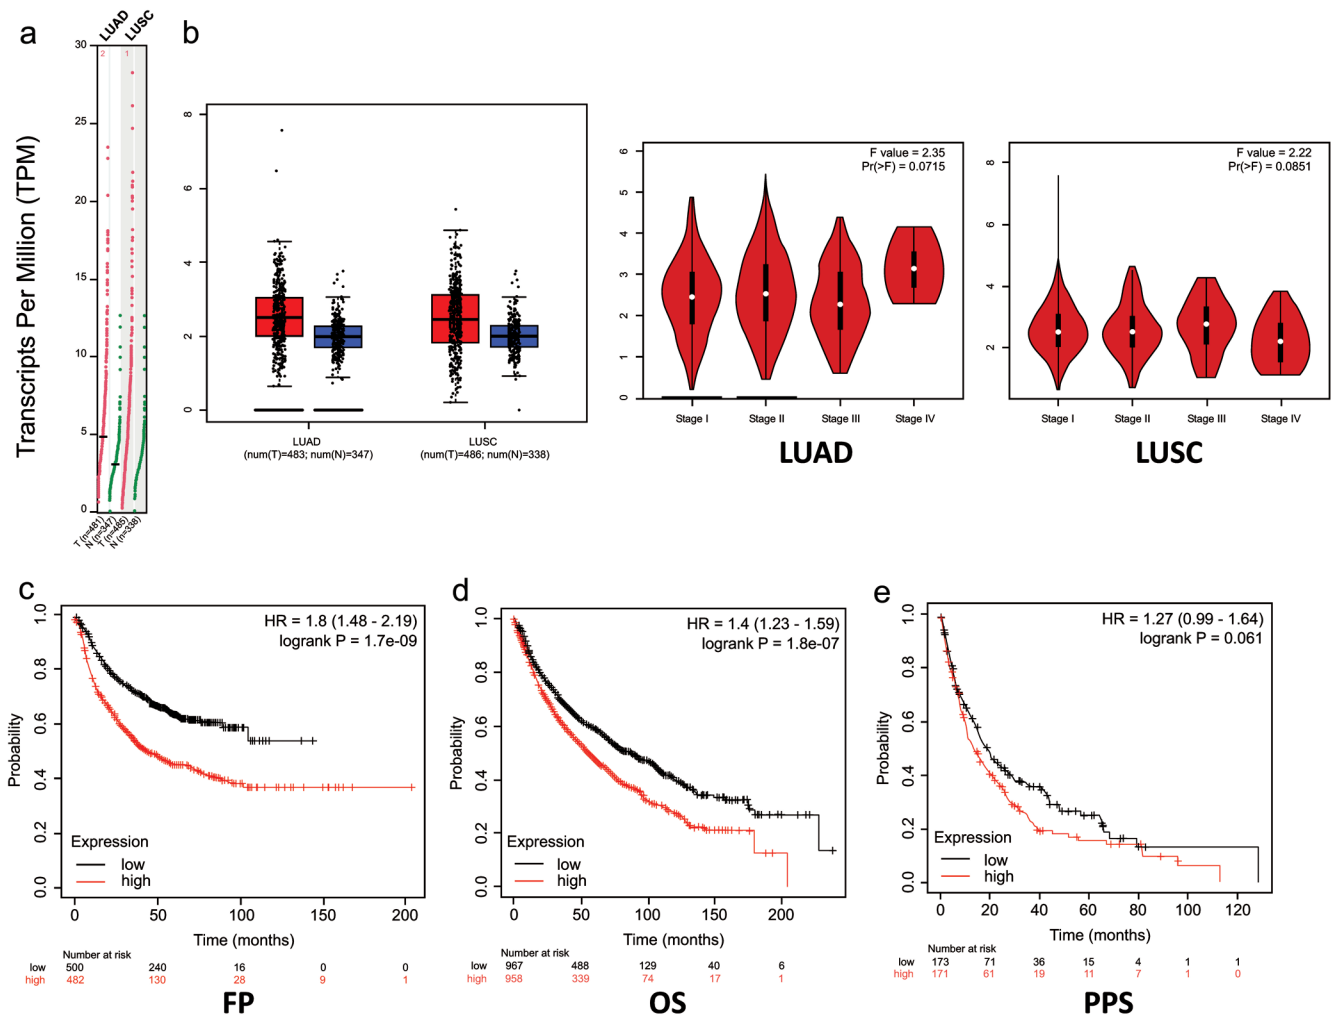

Fig. 2. RUNX2 predicted worse survival in lung cancer patients. The expression level of RUNX2 was increased in lung adenocarcinoma and squamous cell lung carcinoma (a–b) compared with normal lung samples. No significant relationship was found in lung adenocarcinoma (c) and squamous cell lung carcinoma (d) tumor stage with RUNX2 expression level using GEPIA. Increased RUNX2 mRNA level was closely related to a worse FP and OS according to Kaplan-Meier plots (e–g) of patients with lung cancer.

RUNX2 is a lineage-specific transcription factor which is essential in bone development.³¹ However, emerging evidence has indicated that RUNX2 may be a pivotal oncogene in tumorigenesis in recent years. The oncogenic potential of RUNX2 was first demonstrated in T-cell lymphoma.³² After that, a large number of experiments have since proven the involvement of RUNX2 in tumorigenesis.^{11,33,34} In the initial step of tumor formation, RUNX2 was overexpressed and caused abnormal activation of pathways like PI3K/Akt, Wnt, TGF- β , BMP, MAPK/ERK and Notch, MET, which were a hallmark of various types of cancers.³⁵ RUNX2 was documented to be increased in tumor cells and had a negative prognostic value in cancers of the thyroid, breast, colon and prostate.^{13,36,37} For example, it was reported that upregulated levels of RUNX2 accelerated prostate cancer aggressiveness by potentiating tumor cell progression and metastasis through promoting filopodia and adhesion in cancer cells.^{13,33} In T cell lymphomas, highly expressed RUNX2 contributed to the increased transcriptional activity of genes that accelerate survival, growth, and metastasis in the cancer cells.³⁸ In pituitary tumors, RUNX2 upregulated the tumor-promoter and inhibited tumor-suppressors, which facilitate

bone metastasis.³⁹ In advanced thyroid, breast and prostate cancer, increased RUNX2 could dramatically accelerate tumor metastasis.^{10,11} These above studies revealed that RUNX2 can act as a potential oncogene and therapeutic target in various types of cancers.

Actually, it was demonstrated that downregulated RUNX2 could inhibit tumor development via suppressing the EMT process of tumor cells and blocking cell proliferation and invasion in cervical cancer.¹² Downregulated RUNX2 in metastatic prostate and breast cancer cells could significantly reduce tumor metastasis.^{11,13} RUNX2 knockdown could effectively increase esophageal carcinoma cell apoptosis, inhibit cell invasion and eventually suppress tumor enlargement and metastasis.¹⁴

LC is one of the most common malignancies leading to substantial mortality worldwide, because of a high proportion of LC patients diagnosed in an advanced stage.⁴⁰ Therefore, new diagnostic markers and therapeutic targets for LC are urgently required. The relationship between the dysregulated expression of RUNX2 and LC has been partly reported. It was yielded that RUNX2 overexpression could promote EMT and increase the migratory and invasion capacity of LUAD cells.¹⁸ Targeting RUNX2 could inhibit LC

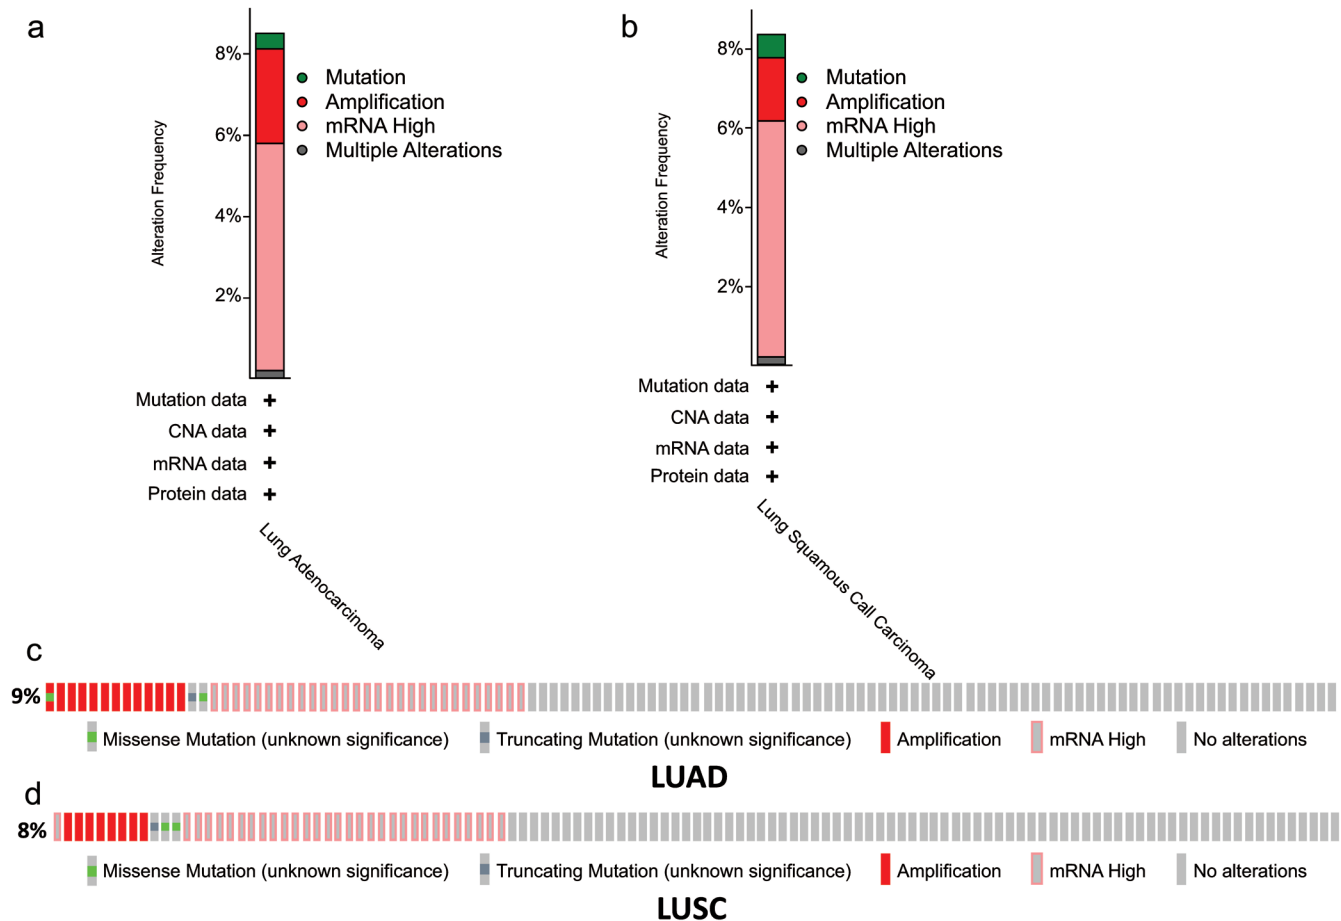

Fig. 4. Analysis of RUNX2 and the altered neighbor genes in lung cancer patients using the cBioPortal database. The RUNX2 alterations and neighbor genes altered by RUNX2 alterations in LUAD (a, c) and LUSC (b, d).

cell growth and greatly reduce tumor volume and weight.^{19,20}

In recent decades, bioinformatic analyses are increasingly applied to explore the relationships between genes and cancers. Although the function of RUNX2 in the tumorigenesis and the prognostic values in many cancers have been partially validated, further bioinformatics analysis of LC and RUNX2 has not been

performed. The current study is a first attempt to explore the mRNA and protein expression, potential functions and distinct prognostic values of RUNX2 in LC.

RUNX2 was reported to overexpress in primary or metastatic LC samples compared to that of normal tissue samples.¹⁸ In the present study, ONCOMINE and GEPIA databases manifested the
